

Module 4: Deterministic Blocking

Rebecca C. Steorts

joint with Olivier Binette

Reading

- ▶ Binette and Steorts (2020)
- ▶ Steorts, Ventura, Sadinle, Fienberg (2014)
- ▶ Murray (2016)

Agenda

- ▶ Data Cleaning Pipeline
- ▶ Blocking
- ▶ Traditional Blocking
- ▶ Probabilistic Blocking

Load R packages

```
knitr::opts_chunk$set(echo = TRUE,  
                        fig.width=4,  
                        fig.height=3,  
                        fig.align="center")  
  
library(RecordLinkage)  
library(blink)  
library(italy)  
library(tidyverse)
```

Data Cleaning Pipeline

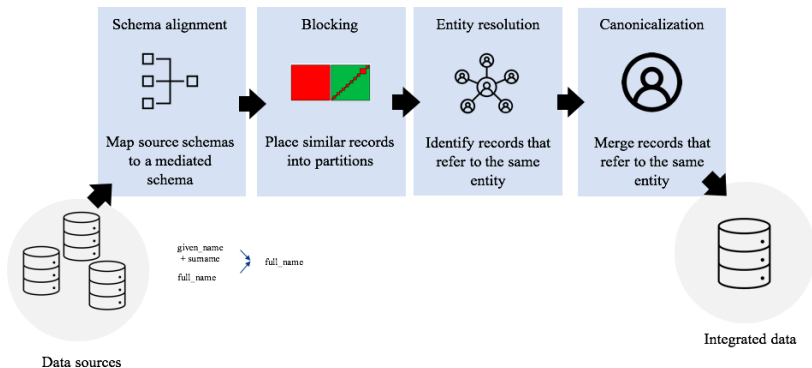

Figure 1: Data cleaning pipeline.

Blocking

Figure 2: Left: All to all record comparison. Right: Example of resulting blocking partitions.

Blocking

- ▶ Blocking partitions similar records into partitions/blocks.
- ▶ ER is only performed within each blocks.

Traditional Blocking

- ▶ A deterministic (fixed) partition is formed based upon the data.
- ▶ A partition is created by treating certain fields that are thought to be nearly error-free as fixed.
- ▶ Benefits: simple, easy to understand, and fast to implement.
- ▶ Downsides: the blocks are treated as error free, which is not usually accurate and can lead to errors in the ER task that cannot be accounted for.

Example: Blocking on date of birth year.

Probabilistic Blocking

- ▶ A probability model is used to cluster the data into blocks/partitions.

Example: Fellegi-Sunter (1969), or Locality Sensitive Hashing

Under both blocking approaches, record pairs that do not meet the blocking criteria are automatically classified as non-matches.

Example: Traditional blocking

Figure 3: All-to-all record comparisons (left) versus partitioning records into blocks by lastname initial and comparing records only within each partition (right).

Example: RLdata500

```
library(RecordLinkage)
data(RLdata500)
head(RLdata500)
```

##	fname_c1	fname_c2	lname_c1	lname_c2	by	bm	bd
## 1	CARSTEN	<NA>	MEIER	<NA>	1949	7	22
## 2	GERD	<NA>	BAUER	<NA>	1968	7	27
## 3	ROBERT	<NA>	HARTMANN	<NA>	1930	4	30
## 4	STEFAN	<NA>	WOLFF	<NA>	1957	9	2
## 5	RALF	<NA>	KRUEGER	<NA>	1966	1	13
## 6	JUERGEN	<NA>	FRANKE	<NA>	1929	7	4

RLdata500 (Continued)

```
# Total number of all to all record comparisons  
choose(500,2)
```

```
## [1] 124750
```

RLdata500 (Continued)

```
# Block by last name initial
```

```
last_init <- substr(RLdata500[, "lname_c1"], 1, 1)  
head(last_init)
```

```
## [1] "M" "B" "H" "W" "K" "F"
```

```
# Total number of blocks
```

```
length(unique(last_init))
```

```
## [1] 20
```

RLdata500 (Continued)

```
# Total number of records per block  
recordsPerBlock <- table(last_init)  
head(recordsPerBlock)
```

```
## last_init  
##  A  B  D  E  F  G  
##  5 56  2  6 38 12
```

RLdata500 (Continued)

```
# Block sizes can vary  
plot(recordsPerBlock,  
      cex.axis=0.6, xlab="", ylab="")
```

RLdata500 (Continued)

Total number of records pairs per block

```
choose(recordsPerBlock, 2)
```

```
## last_init
```

```
##      A      B      D      E      F      G      H      J      K      L      M
##    10 1540      1     15    703     66    496     28 1035     78 2850
##      T      V      W      Z
##      1     21 1326     10
```

Reduction on comparison space

```
sum(choose(recordsPerBlock, 2))
```

```
## [1] 14805
```

RLdata500 (Continued)

What is the overall dimension reduction from the original space to the reduced space induced by blocking?

Recall the original space of comparisons was

```
choose(500, 2)
```

```
## [1] 124750
```

We have reduced the number of comparisons to

```
sum(choose(recordsPerBlock, 2))
```

```
## [1] 14805
```

How do we calculate the reduction ratio?

The reduction ratio is

RR = % comparisons eliminated by blocking.

```
(choose(500, 2) - sum(choose(recordsPerBlock, 2))) /  
choose(500, 2)
```

```
## [1] 0.8813226
```

How do we calculate the reduction ratio (via a function)?

```
reduction.ratio <- function(block.labels) {  
  n_all_comp = choose(length(block.labels), 2)  
  n_block_comp = sum(choose(table(block.labels), 2))  
  
  (n_all_comp - n_block_comp) / n_all_comp  
}  
  
reduction.ratio(last_init)
```

```
## [1] 0.8813226
```

Pairwise Precision

```
labels = unique(last_init)

# Number of matching pairs among blocks
n_matches = sapply(labels, function(label) {
  # Records in a given blocks
  records = which(last_init == label)
  # Number of matches in that block
  sum(duplicated(identity.RLdata500[records]))
})

# Total number of pairs
n_pairs = sum(choose(table(last_init), 2))

sum(n_matches) / n_pairs

## [1] 0.003377237
```

Pairwise Precision

```
precision <- function(block.labels, IDs) {  
  labels = unique(block.labels)  
  
  # Number of matching pairs among blocks  
  n_matches = sapply(labels, function(label) {  
    records = which(block.labels == label)  
    sum(duplicated(IDs[records]))  
  })  
  
  # Total number of pairs  
  n_pairs = sum(choose(table(block.labels), 2))  
  
  sum(n_matches) / n_pairs  
}  
  
precision(last_init, identity.RLdata500)
```

```
## [1] 0.003377237
```

Pairwise Recall

```
recall <- function(block.labels, IDs) {  
  precision(IDs, block.labels)  
}
```

Italian Survey on Household and Wealth (SHIW)

We will now explore a case study to the SHIW

SHIW

- ▶ The Italian Survey on Household and Wealth (SHIW) is a sample survey 383 households conducted by the Bank of Italy every two years (2008 and 2010).
- ▶ The data set is anonymized to remove first and last name (and other sensitive information).

SHIW

The following attribute information is available:

- ▶ PARENT (parental status)
- ▶ GENDER
- ▶ ANASC (year of birth)
- ▶ NASCREG (working status)
- ▶ CIT (employment status)
- ▶ ACOM4C (branch of activity)
- ▶ STUDIO (town size)
- ▶ Q (quality of life status)
- ▶ QUAL (whether or not Italian national)
- ▶ SETT (highest educational level obtained)
- ▶ IREG (region of Italy)

Explore Data

```
head(italy08) # first year of SHIW
```

##	id	PARENT	SEX	ANASC	NASCREG	CIT	ACOM4C	STUDIO	Q	QUAL	SETT	IREG
## 1	1040021	1	2	1948	16	1	0	5	1	2	3	16
## 2	1040022	10	2	1952	16	1	0	7	1	2	3	16
## 3	1110521	1	1	1972	20	1	2	5	1	1	4	20
## 4	1110522	3	1	1935	20	1	2	2	3	6	5	20
## 5	1110523	3	2	1941	20	1	2	3	3	6	5	20
## 6	119401	1	1	1941	7	1	0	4	3	6	5	7

Explore Data

```
head(italy08) # second year of SHIW
```

##	id	PARENT	SEX	ANASC	NASCREG	CIT	ACOM4C	STUDIO	Q	QUAL	SETT	IREG
## 1	1040021	1	2	1948	16	1	0	5	1	2	3	16
## 2	1040022	10	2	1952	16	1	0	7	1	2	3	16
## 3	1110521	1	1	1972	20	1	2	5	1	1	4	20
## 4	1110522	3	1	1935	20	1	2	2	3	6	5	20
## 5	1110523	3	2	1941	20	1	2	3	3	6	5	20
## 6	119401	1	1	1941	7	1	0	4	3	6	5	7

Reformat Data

```
id08 <- italy08$id
id10 <- italy10$id
id <- c(italy08$id, italy10$id) # combine the id
italy08 <- italy08[-c(1)] # remove the id
italy10 <- italy10[-c(1)] # remove the id
italy <- rbind(italy08, italy10)
head(italy)
```

##	PARENT	SEX	ANASC	NASCREG	CIT	ACOM4C	STUDIO	Q	QUAL	SETT	IREG
## 1	1	2	1948	16	1	0	5	1	2	3	16
## 2	10	2	1952	16	1	0	7	1	2	3	16
## 3	1	1	1972	20	1	2	5	1	1	4	20
## 4	3	1	1935	20	1	2	2	3	6	5	20
## 5	3	2	1941	20	1	2	3	3	6	5	20
## 6	1	1	1941	7	1	0	4	3	6	5	7

Your turn

- ▶ Construct a blocking criterion for the SHIW data set.
- ▶ Provide code to construct the blocks
- ▶ Are your blocks well balanced?
- ▶ What is the reduction ratio?
- ▶ What is the pairwise recall and precision?
- ▶ Would you recommend your blocking criterion for an ER task?
Why or why not.

Hint: You might consider blocking on gender, regions (in Italy), or combinations of these. What do you find?

Your turn solution

Let's block on gender.

```
# block by gender  
blockByGender <- italy$SEX  
recordsPerBlock <- table(blockByGender)  
head(recordsPerBlock)
```

```
## blockByGender  
##      1      2  
## 14442 12993
```

Your turn solution

The block sizes are similar. But note, they are still quite large.

```
# Checking block sizes  
plot(recordsPerBlock,  
      cex.axis=0.6, xlab="", ylab="")
```

Your turn solution

```
print(rr <- reduction.ratio(blockByGender))
```

```
## [1] 0.4986234
```

We have reduced the overall space by roughly 50 percent.

Your turn solution

```
precision(blockByGender, id)
```

```
## [1] 3.599727e-05
```

```
recall(blockByGender, id)
```

```
## [1] 0.9113109
```

This is not an optimal blocking criterion as ideally, we would want both the precision and recall to be close to 1.

Your turn solution

Let's block on the twenty regions in Italy.

```
blockRule <- (italy$IREG)
(recordsPerBlock <- table(blockRule))
```

```
## blockRule
##   1    2    3    4    5    6    7    8    9   10   11   12   13   14   15   16
## 2530  164 2875  645 1938  789 1050 2497 2203 1070 1235 1443  707  478 2329 1461
##   17   18   19   20
##  455  595 1678 1293
plot(recordsPerBlock,
     cex.axis=0.6, xlab="", ylab="")
```

```
print(rr <- reduction.ratio(blockRule))
```

```
## [1] 0.9339148
precision(blockRule, id)
```

Your turn solution

Let's block on a combination of gender and region.

Trying to make this work using tidyverse as it seems more elegant.

Your turn solution

```
recordsPerBlock <- italy %>%  
  group_by(IREG, SEX) %>%  
  summarise(count = n(), .groups="drop") %>%  
  group_by(count) %>%  
  ggplot() +  
  geom_histogram(aes(count))
```

Your turn solution

```
italy %>%  
  group_by(italy$IREG, italy$SEX) %>%  
  summarise(count = n()) %>%  
  group_by(count) %>%  
  ggplot() +  
  geom_histogram(aes(count))
```

Your turn solution

```
{r} # grouping <- group_by(italy, italy$IREG,  
italy$SEX) # recordsPerBlock <-  
summarise(italyBlocked, count=n()) #  
table(recordsPerBlock$count) # print(rr <-  
reduction.ratio(recordsPerBlock$count)) #  
precision(recordsPerBlock$count, id) #  
recall(recordsPerBlock$count, id) #
```
